ABSTRACT

A group of chemicals known as surfactants are widely used in industries. Their presence in any formulation, albeit little, exhibited superior functionality of the end-products. The dual hydrophobic and hydrophilic moiety of the structure have been shown to be responsible for reduction of surface/interfacial tension and formation of micelles. In this work, a chemical flooding method using sodium dodecyl sulphate, SDS and its mixture with gum arabic, were carried out to study the recovery and efficiency of extracting the residual oil from the oil reservoirs. Two sets of experiments namely SDS and its mixture with gum arabic flooding at concentrations of SDS between 0.1-0.6 percent by weight are conducted. The percentage of gum arabic used is 16 percent by weight. Results shows that the use of SDS-Gum arabic flooding method yielded higher extraction of oil about 4.0 percent compared to SDS flooding. This suggests that the use of SDS and gum Arabic mixture is more efficient in increasing the amount of oil recovery.

Keywords: Enhanced Oil Recovery, Chemical Flooding, Gum Arabic, Viscosity, Surface Tension.

INTRODUCTION

Oil production has dramatically decreased day by day. With the passing of present time, it is matter of time that oil field discovery is not possible, while the demand for oil is increasing day by day, both in the developed and developing countries. This deficit forced the oil industry to enhance the oil recovery, where less accessible through oil recovery methods. One of the methods in enhanced oil recovery, EOR is surfactant flooding method employed to recover part of the residual oil left behind by water

flooding. Surfactant flooding has been around for more than four decades and several reviews have been reported with the recent ones on surfactant flooding¹, foam assisted² and nanotechnology for EOR³. Surfactants are special compounds that combine hydrophobic and hydrophilic molecules that constitute stable configuration in water and crude oil interfaces. The mixture of oil to a surfactant systems to become microemulsions is another interesting area of research⁴. Surfactants reduced the surface tension between water and crude oil, reduce capillary force and facilitates oil mobilization

when surfactant injected with water. Therefore, the choice of surfactants becomes crucial due to the complexity of the parameters involved in the recovery process such as temperature, salinity, pH, cost effectiveness, interfacial tension and the structure of the surfactants^{5,6}. Another method is the polymer flooding method. The polymers help increase the viscosity of the displacing water to drive the displacing oil to the production well⁷. By that the usage of water is greatly reduced and oil recovery is enhanced, hence more cost effective compared to only water flooding method. These surfactant and polymer flooding are termed as chemical flooding⁸.

The use of surfactant in the oil recovery is well documented¹⁻³. However, several works reported different result by using surfactant and polymer. Feng *et al.*,⁹ reported that use of optimal surfactant concentration in oil field 22% additional oil was recovered by using alkali lignin and partially hydrolyte polyacrylamide (HPAM). It was also reported that due lack enough injection wells in the reservoir. The result was not ideal. Abhijith *et al.*,¹⁰ conducted the same experiment, where the additional oil recovery was 20 % for surfactant flooding and 23% for surfactant-polymer flooding. While, Teepols as surfactant and polymer (gum Arabic) for EOR shows an additional oil recovery of 19%¹¹⁻¹³, where Abidin *et al.*,¹⁴ investigated 20% oil recovery. Santanna *et al.*,¹⁵ applied EOR method which performed the maximum efficiency in oil recovery measuring 21.5%. This result demonstrated the efficiency of microemulsion in oil recovery which is in direct effect of the viscosity whereby oil was more easily recovered due to lower mobility in the porous medium.

In this present work, it is not meant to be an argumentative in nature but to present the findings from a combination of a surfactant and a polymer at various concentration of surfactant in order to study the effect on the oil recovery and efficiency of extracting the residual oil from the oil reservoirs. The surfactant and polymer used are sodium dodecyl sulphate, SDS and gum arabic, respectively. Standard equipment such viscometer, surface tensiometer and sand pack PVC reactor are used to elucidate the physical parameter such as viscosity, surface tension and the amount of extracted oil.

MATERIALS AND METHODS

Materials

The chemicals were of analytical grade and used as received. Arabic gum were purchased from local market and the clean dry silica sand (0.2–0.4 mm) were collected from Terengganu sea beach.

Preparation surfactant- polymer solution

Surfactant and polymer solution were prepared with brine by surfactant of 0.1% - 0.6% by weight concentration with 16% gum arabic (Table 1) using a magnetic stirrer properly mixed and allowed to stay 72 h to hydrate achieved a desired viscosity to allow for Gum Arabic. The magnetic stirrer performed at 600 (rpm) speed. After performing magnetic stirrer, the sample using the vacuum filter pump for removed by non-dissociated particles. The viscosities were measured using the Brookfield DV-I Digital Viscometer Model LVDV-I

Preparation surfactant solution

Surfactant solution was prepared with brine by surfactant of 0.1% - 0.6% by weight concentration using a magnetic stirrer properly mixed and allowed to stay 36 hours. The magnetic stirrer performed at 200 (rpm) speed. After performing magnetic stirrer, the sample using the vacuum filter pump for removed by non-dissociated particles. The surface tension with and without surfactant was measured by using Force Tensiometer Model Sigma701.

Table 1. Composition of solution for viscosity measurement

Solution No	Composition
1	Water
2	SDS (0.1 wt %) + NaCl (3 wt %) + gum Arabic (16 wt %)
3	SDS (0.2 wt %) + NaCl (3 wt %) + gum arabic (16 wt %)
4	SDS (0.3 wt %) + NaCl (3 wt %) + gum arabic (16 wt %)
5	SDS (0.4 wt %) + NaCl (3 wt %) + gum arabic (16 wt %)
6	SDS (0.5 wt %) + NaCl (3 wt %) + gum arabic (16 wt %)
7	SDS (0.6 wt %) + NaCl (3 wt %) + gum arabic (16 wt %)

Preparation of sand pack column

The core-flood reactor (sand pack pvc reactor) was used in all enhance oil recovery tests, which measures 250 cm³ of bulk volume along with 100 cm in length and 5.08 cm diameter. The core-flood reactor was cleaned thoroughly with water and sodium chloride to prevent any other impurity

during flood testing. Then the reactor was compact (rod) bound with water using dry sand particle (0.2-0.4 mm). The amount of water used for making 100% saturation of sand pack during this core-flood column is the amount of packing represented pore volume (PV). The ratio between this pore volume (90-90.1 cm³) and bulk volume (250 cm³) is the porosity (%) of the sand pack column. Before leaving any extra injection, the sand pack reactor lasts 1-2 hours before the experimental temperature (353.15 K)

Procedure for EOR experiments

The experimental setup used for the investigation, which includes a horizontal PVC core-flood reactor, Peristaltic pump and collection flask. Peristaltic pump (Model: Watson Marlow 120S, Display Type: Digital, Maximum Pressure: 30 psi, Motor Type: Brushless DC) was used in the injection of fluids, such as water, crude oil, SDS solution, and polymer solution. Peristaltic pump was used to control the flow rate of flood during the flow rate where all the flood tests were placed at 3m/min (3 cm/minute). Once the sand pack was ready, the column was pre-flushed using the tap water to ensure uniform water involvement, in which the absolute accessibility of the injection fluid (water) was done. During each flood test, the pressure drops (pressure difference between the inlet and outlet) is observed using injection fluid peristaltic pumps for each sequentially. Then, crude oil injection starts in the sand pack column and to ensure complete involvement, the production side (collection flask) continues until the produced water is supplied. During this process, the amount of water produced in the collection flask is considered as the in the original place (OOIP), i.e. the amount of water equivalent to oil saturation. For all EOR tests, initial water saturation and initial oil saturation are calculated using OOIP and PV as shown in the following Equation. (1a) and (1b),

$$S_{wi} = \left(\frac{OOIP}{PV} \right) \times 100 \quad (1a)$$

$$S_{oi} = \left(\frac{PV - OOIP}{PV} \right) \times 100 \quad (1b)$$

Procedure for EOR studies for SDS and SDS-Gum arabic flooding

Preceding to tertiary (chemical) oil recovery, the oil saturated sand pack was subjected to oil recovery of water injection was initiated in the oil saturated sand pack to mimic the secondary oil

recovery operation and was continued until there was no further oil production. The residual oil, which was trapped in the sand pack was called as the remaining oil and is the target for tertiary oil recovery (enhanced oil recovery) process using different type of chemical agents, such as only SDS solution (3 wt% NaCl + 0.1 wt% to 0.6 wt% of SDS), SDS + polymer solution (3 wt% NaCl + 0.1 wt% to 0.6 wt% SDS + 16 wt% of polymer). At the end of each experiment, water flooding was performed to ensure the removal of the chemicals from the sand pack column shown in Figure 1.

Fig. 1. Schematic representation of the experimental set-up used for the flooding experiment

RESULTS AND DISCUSSION

Effect of SDS on viscosity

Viscosity has the most significant impact on water flooding. If viscosity is high, the process efficiency of water displacing oil is high. If viscosity is low, the efficiency of water displacing oil would be low. In order to illustrate the effect of SDS on the viscosity various solution at varied concentration of SDS were prepared and different % of SDS (Table 1) and plotted as shown in Fig. 2. The result shows that an increment of viscosity with the concentration of solution. This reflect that the viscosity is dependent with the amount of SDS in the solution with a volume 13.1 cP at 0.6 % of SDS.

The increased in viscosity as explained by Hongyan *et al.*,¹⁶, increase the sweep efficiency of the system.

Effect of SDS on surface tension

Figure 3 shows the effect of various

surfactant concentrations in surface tension on oil-brine system. The temperature was set at 90°C with ambient pressure. It indicates that 0.1% - 0.6 % by weight which is equivalent to 0.003-0.02 mol/L of SDS were used to measure the surface tension. The result showed that the increment %weight of SDS reduced the surface tension until at constant with maintaining the CMC value. This indicates the CMC value of SDS is 0.008 mol/L and it is in accordance with CMC reported in the literature¹⁷. The ideal range of the percent of surfactant is also on agreement with previously reported to be between 0.1-0.5 % by weight¹⁸.

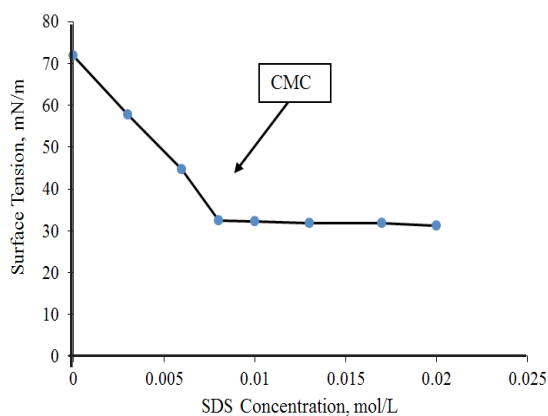

Fig. 2. Viscosity for the water -polymer/surfactant system

SDS and SDS-Gum arabic flooding for additional oil recovery

Two series of flooding experiments have been conducted to investigate the enhancement

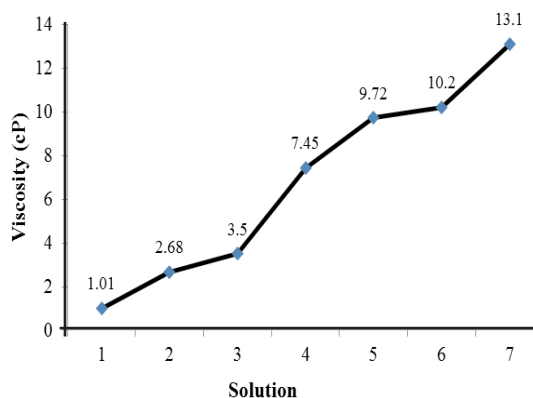

Fig. 3. The variation of surface tension with the concentration of SDS

of oil recovery by using SDS, NaCl and polymer (gum Arabic). In order to compare the enhancement of oil recovery, firstly flooding experiment was conducted by using water for oil recovery. The respective values of S_{wi} and S_{oi} for both flooding systems are calculated and tabulated (Table 2 and 3, for SDS-Gum Arabic and SDS flooding respectively). The amount of oil recovery by water flooding were found to be minimum 59.0% and maximum 61.8%. Then the SDS-gum Arabic is performed to recover the remaining oil and it is observed that additional oil is recovered with a minimum of 13.0% and maximum of 25.0% (Table 2). Similar experiment is repeated but for SDS flooding (Table 3). The results show that after the water flooding, the remaining oil recovered with a minimum of 15.0% and a maximum recovery of 21.0% (Table 3).

Table 2: The values calculated for SDS-Gum arabic flooding system

Expt No	SP Slug Design	Oil recovery by water flooding(%)	Additional oil recovery by SP flooding(%)	S_{wi}	Saturation% S_{oi}	S_{or}
1	SDS (0.1 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	59.0	13.0	12.8	87.1	24.7
2	SDS (0.2 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	59.0	14.9	15.6	84.3	22.1
3	SDS (0.3 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	61.4	16.4	13.9	86.0	21.0
4	SDS (0.4 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	60.8	20.0	14.4	85.5	21.0
5	SDS (0.5 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	61.8	25.0	15.2	84.7	20.7
6	SDS (0.6 wt %) + NaCl (3 wt %) + (16 wt %) gum Arabic	61.0	24.3	15.5	84.4	19.7

Table 3. The values calculated for SDS flooding system

Expt No	Surfactant Slug Desing	Oil recovery by water flooding(%)	Additional oil recovery by SP flooding(%)	S_{wi}	Saturation% S_{oi}	S_{or}
1	SDS (0.1 wt %) + NaCl (3 wt %)	59.0	15.0	17.9	82.0	20.7
2	SDS (0.2 wt %) + NaCl (3 wt %)	58.9	16.1	18.8	81.1	19.1
3	SDS (0.3 wt %) + NaCl (3 wt %)	59.2	17.0	18.9	81.0	19.0
4	SDS (0.4 wt %) + NaCl (3 wt %)	58.7	19.4	19.0	81.0	18.9
5	SDS (0.5 wt %) + NaCl (3 wt %)	58.8	20.8	19.0	80.3	18.8
6	SDS (0.6 wt %) + NaCl (3 wt %)	60.0	21.0	20.0	79.9	16.6

Effect of SDS concentration on SDS and SDS-Gum arabic flooding

Figure 4 is plotted in order to facilitate understanding on the effect of SDS concentration on both SDS and SDS-Gum Arabic flooding, The result shows that incremental SDS concentration increases the additional oil recovery with minimum value of 13.0% at the 0.1% SDS concentration and a maximum of 25.0% at 0.5% surfactant concentration for the SDS-Gum arabic flooding (solid circles of Fig. 4). It is also observed that the highest % of additional oil recovery was found at 0.5% concentration of SDS. This result shows that OOIP is increased by increasing surfactants in the surfactant-polymer slug. The excessive recovery of excess oil is achieved at 0.5% of the recovery and can be attributed to the formation of micelles at CMC as reported earlier by Solomon *et al.*,¹⁹. While the effect of SDS on SDS flooding (solid squares of Fig. 4) show similar trend with incremental surfactant concentration increases the additional oil recovery with a minimum value at 15.0% and maximum

at 21.0%. In the comparison surfactant-polymer flooding the additional oil recovery minimum 13.0% and maximum 25.0%. Therefore, it can be concluded that the additional oil recovery for SDS-Gum arabic flooding is more effective than only SDS flooding. This is due to the synergic effects of reduction of surface tension by surfactant and improvement of mobility ratio by polymer solution as explained earlier.

CONCLUSION

In this chemical flooding study, it can be concluded that the concentration of SDS in SDS-Gum arabic slug can affect the quantity of oil recovered. Polymer (Gum Arabic) and SDS are suitable for the mobility control of the enhanced oil recovery process. Using small amount of surfactant reduces the surface tension of liquid (water) appreciably, which increases oil recovery from the oil bank. In addition, the use of gum arabic increases the sweep efficiency by reducing the mobility ratio. The SDS flooding method the oil recovery by approximately 21.0 percent. However, the SDS-Gum arabic system increases the oil recovery by 25.0 percent. This shows that mixtures of SDS-Gum arabic method the recovery oil is increased by 4.0 percent increase compared to SDS flooding.
